ABSTRACT

Reaction of various N-enoyl oxazolidinones 5a−f with N-aminophthalimide and lead tetraacetate in the presence of camphor-derived chiral ligands provides the desired N-phthalimidoaziridines 6a−f in good to high enantiomeric excess (67−95% ee) at 0 °C within 15 min. The absolute stereochemistry of the corresponding aziridine derivatives was established by chemical correlations.

The synthesis of chiral nonracemic aziridines has received much attention in recent years. They are not only attractive intermediates for organic synthesis but also can serve as useful chiral auxiliaries, chiral reagents, and chiral ligands in asymmetric synthesis.1 Among the various routes that have been developed so far, the use of copper-catalyzed addition from a range of alkenes and (N-(p-toluenesulfonyl)imino)-phenyliodinane (PhI=NTs) is of particular potential.2 The disadvantage of this aziridination procedure is the necessity of using the expensive and inconvenient PhI=NTs as the nitrenoid source.3 The reaction of chiral 3-acetoxyamino-quinazolinone derivatives with various alkenes in the presence of camphor-derived ligands provides aziridines with excellent diastereoselectivities.4 The stereospecific aziridination of alkenes with chiral nitridomanganese complexes provides the desired products with high enantioselectivity.5 Vederas et al. have reported the oxidation of N-aminophthalimide with lead tetraacetate in the presence of N-enoylbornane[10,2]-sultams, resulting in stereospecific syn addition to afford the corresponding N-phthalimidoaziridines with 33−95% de.6

We have applied the analogous process by reacting various chiral camphor N-enoyl pyrazolidinones with N-aminophthalimide in the presence of lead tetraacetate.7 The desired N-phthalimidoaziridines were obtained with high levels of diastereoselectivities (up to >90% de) with excellent material yields (86−95%) at 0 °C in 5 min. In continuation with our work in designing novel camphor-derived ligands for asymmetric synthesis, we were intrigued by the potential of using

a lead tetraacetate-mediated chiral ligand for the preparation of enantiomerically enriched aziridines. The novel camphor-derived carboxylic acid containing ligands 1–4 (Figure 1) were prepared from this laboratory and were proven to be synthetically useful in catalytic synthesis. In this regard, the use of lead tetraacetate complexed with enantiopure ligand might aziridinate alkene enantioselectively in the presence of N-aminophthalimide. The carboxylic acid moiety may serve as a good donor group by taking advantage of the oxophilic nature of lead tetraacetate. Since the aziridination takes place extremely fast (5 min at 0 °C) under these reaction conditions, the oxidative cleavage of the chiral ligand by lead tetraacetate may not interfere with the reaction.

The use of 1,3-oxazolidin-2-one as an excellent achiral template in a variety of enantioselective transformations has been documented. The 3-((E)-3-phenyl-2-propenyl)-1,3-oxazolidin-2-one 5a was chosen as a probe substrate for this reaction to avoid the potential N-interconversion of the adduct. Thus, treatment of 5a with ligand 1 with lead tetraacetate in the presence of N-aminophthalimide provide the desired aziridines in excellent chemical yields (Table 1, entry 1). The relative configuration of the aziridine moiety was assigned by 1H NMR spectral analysis (δtrans = 5.2 Hz) which, however, reveals a mixture of two N-invertomers in a ratio of ca. 9:1. The structure of the major N-invertomer with the phthalimido group and the 2-carboxyl group cis-disposed in the aziridine ring system was confirmed by single-crystal X-ray analysis.

The stereoselectivity was determined to be 75% ee by HPLC analysis using a Daicel Chiralcel Chiralpak AD column. The use of chiral ligands 2 and 3 gave the desired aziridines in low to nil stereoselectivities with excellent material yields (entries 2 and 3). To our surprise the use of chiral ligand 4 provided 6a in 95% ee under the same reaction conditions (entry 4). The newly generated stereogenic centers were determined to be in the (2R,3S) configuration by chemical correlations with the known aziridine. Thus, treatment of aziridine 6a with camphor pyrazolidinone (5.0 equiv; DMAP, CH3CN, rt, 12 h; 80% yield) gave the known N-phthalimidoaziridine 7a (Scheme 1). Spectroscopic data analyses (1H, 13C NMR) indicate that both compounds are identical, and optical rotation measurements confirm the absolute configurations [α]D = −86.1° (c = 1, CHCl3), with a value comparable with that of a previously prepared compound: [α]D = −88.0° (c = 1, CHCl3). The use of (+)-tartaric acid gave 6a in 42% ee, favoring the opposite stereochemistry (entry 5). Next we studied the solvent effect. The use of CHCl3 provided the desired product in a comparable result while the stereoselectivity diminished significantly when THF was used (entries 6 and 7).

To further determine the feasibility of this system, various N-enoyl oxazolidinones 5b–f were then studied under the optimum conditions, and the results are tabulated in Table 1.

* All reactions are conducted using activated alkenes (0.46 mmol), Pb(OAc)4 (0.72 mmol), chiral ligand (0.72 mmol), and N-aminophthalimide (0.68 mmol) in the solvent indicated at 0 °C for 5 min. Determined by HPLC analysis using a Daicel Chiralcel Chiralpak AD column. Absolute stereochemistry is established by chemical correlation (see text).

**Scheme 1.** Formation of Camphor Pyrazolidinone-Derived N-Phthalimidoaziridines 7a and 7c

![Scheme 1](image)
isolated when a \( \beta \) \( \beta \)-dimethyl substituent was used (5g: \( R^1 = H, R^2 = R^3 = Me \)). Toward this end, treatment of 5g with chiral ligand 4, N-aminophthalimide, and Pb(OAc)\(_4\) in CH\(_2\)Cl\(_2\) affords compound 8 in 88% yield. The structure was initially assigned by spectroscopic (\( ^1H \) and \( ^{13}C \) NMR) and HRMS analyses and further confirmed by single crystal X-ray analysis. This was believed to proceed through the opening of the initially formed aziridine ring by a water molecule to give the corresponding amino alcohol 10. This was, in the presence of Lewis acid, followed by attack of the tertiary alcohol on the oxazolidinone carbonyl group and subsequent oxazinanediene ring formation to provide compound 8 (Scheme 3).

2. Thus, the use of N-acryloyloxazolidinone (5b) gave the desired product in 80% ee (entry 1). The \( \beta \)-alkyl substituent provide the desired products in high enantioselectivity (entries 2 and 3). The stereoselectivity drops when an \( \alpha \)-substituent is present. Thus, the use of N-methacryloyloxazolidinone (5e) gave 6e in 67% ee (entry 4).

The oxazolidinone moiety of the substrate plays an indispensable role in this reaction. The use of aryl acrylates and unfunctionalized olefins led either to low stereoselectivity or low chemical yield. For examples, the use of 3-phenylacrylic acid phenyl ester affords the desired product in 80% chemical yield (<10% ee) while the use of cyclohexene gave only a 24% yield. A detailed mechanistic speculation of this reaction is premature at this stage. The coordination of the ligand-mediated Lewis acid to the bidentate acyl oxazolidinone (5f) gave the desired product in 80% ee (entry 1). The absolute stereochemistry was not determined.

An interesting 1,3-oxazinane-2,4-dione derivative, 8, was isolated when a \( \beta \) \( \beta \)-dimethyl substituent was used (5g: \( R^1 = H, R^2 = R^3 = Me \)). Toward this end, treatment of 5g with chiral ligand 4, N-aminophthalimide, and Pb(OAc)\(_4\) in CH\(_2\)Cl\(_2\) affords compound 8 in 88% yield. The structure was initially assigned by spectroscopic (\( ^1H \) and \( ^{13}C \) NMR) and HRMS analyses and further confirmed by single crystal X-ray analysis. This was believed to proceed through the opening of the initially formed aziridine ring by a water molecule to give the corresponding amino alcohol 10. This was, in the presence of Lewis acid, followed by attack of the tertiary alcohol on the oxazolidinone carbonyl group and subsequent oxazinanediene ring formation to provide compound 8 (Scheme 3).
